Chromated Copper Arsenate (CCA) Treated Wood

Chromated copper arsenate (CCA) is an inorganic arsenical (composed of arsenic, chromium and copper) that is used as a wood preservative. In February 2002, the U.S. Environmental Protection Agency (EPA) announced a voluntary phase-out by industry of most residential uses of this arsenic-based wood preservative. The agreement states that beginning in January 2004, CCA-treated wood can no longer be manufactured for decks and patios, picnic tables, playground equipment, walkways/boardwalks, landscaping timbers, or fencing. However, already existing residential CCA-treated wood and structures may continue to be sold and used.

In 1988, when EPA decided to cancel most non-wood uses of the inorganic arsenicals, the agency stated its concern about oncogenicity (cancer), mutagenicity (genetic damage), teratogenicity (birth defects) and acute toxicity. EPA noted that its Office of Health and Environmental Assessment (OHEA) had prepared a report reviewing the existing scientific literature, including “Human epidemiology studies ... [which] provided the most persuasive evidence linking exposure to inorganic arsenic to an increase in cancer in humans.” When EPA finally canceled the last non-wood use of the inorganic arsenicals in 1993, it determined it would not modify its earlier risk/benefit assessment.

Since then, intensive involvement by advocacy groups has led to investigations, hearings and even lawsuits. In December of 2002, Beyond Pesticides filed suit in the District of Columbia District Court to ban all use and production of three major wood preservatives, including CCA (See Pushing to End The Horror of Hazardous Wood Preservatives, Pesticides and You, Winter 2002-2003). In 2003, the Consumer Product Safety Commission (CPSC) responded to a petition, filed by the Environmental Working Group and the Healthy Buildings Network, to cancel CCA for use on playground equipment. By assessing the results of a series of tests wiping surface residues from CCA treated wood, and the amount of time children spend on playground equipment, the Commission found a 2 to 100 per million increased risk of lung or bladder cancer. The US Consumer Product Safety Commission, Briefing Package: Petition to Ban Chromated Copper Arsenate (CCA)-Treated Wood in Playground Equipment (Petition HP 01-3), February 2003.

Routes of exposure

One of the most important factors in determining the hazard of a toxic chemical is an evaluation of actual exposure to the chemical. In the case of CCA, chances of exposure are heightened since the chemical’s use as a wood preservative is so widespread. Exposure through ingestion and inhalation, and to a lesser extent skin absorption, pose risks to both human health and the environment.

Children face especially high risks from exposure since they take in more pesticides relative to body weight than adults. In addition, children have developing organ systems that are more vulnerable and less able to detoxify toxic chemicals. The Minnesota Arsenic Study (MARS), conducted by the Minnesota Department of Health (MDH), finds that children accumulate arsenic at a higher rate than adults. Furthermore, the probability of an effect such as cancer, which requires a period of time to develop after exposure, is enhanced if exposure occurs early in life. Exposure to CCA is heightened by hand-to-mouth behavior, which is well-documented among children. According to the October, 2001 EPA Scientific Advisory Panel (SAP) recommendation, children have an average of 9.5 hand-to-mouth activities per hour for an average of 1-3 hours of play activity. This number has the potential to grossly underestimate the true exposure to active children and to high-risk groups predisposed to increased rates of hand-to-mouth behavior, such as children with Down syndrome (DS).

Exposure through direct contact with wood: The arsenic in CCA-treated wood can be dislodged so that direct contact with wood can lead to exposure. The amount dislodged depends on age and use of the wood, according to the Connecticut Agricultural Experiment Station. Wipe tests done on the horizontal surfaces of three municipal play structures found an average of 8.8 µg/100 cm² arsenic dislodged from the wood. This was less than the average from new wood (40 µg/100 cm²). Tests done on the vertical support beams found higher levels of arsenic compared to the horizontal surfaces and the new samples, showing levels as high as 632 µg/100 cm² and averaging 105 µg/100 cm². A study conducted by the Environmental Working Group examined samples wiped from CCA-treated wood surfaces, collected from an area about size of a four-year old child’s hands. In one quarter of the samples, the amount of arsenic wiped off the surface was at least three times the 10-microgram EPA drinking water limit. Some samples showed up to 250 micrograms of arsenic. This arsenic can be ingested into the bodies of children participating in typical hand-to-mouth behavior or eating. Exposure to arsenic can dramatically increase with normal contact to decks, play sets and other wood treated with CCA.

Exposure through contaminated soil: Leaching of CCA from wood into surrounding soil is well-documented. Arsenic and chromium (VI) have been found to leach in substantial quantities from CCA treated wood. Carcinogenic hexavalent chromium (Cr VI) is known to account for up to 50% of the total chromium in CCA. This chromium is known to leach out of CCA treated wood. A 1997 report by Stilwell and Gorny found that soil around CCA-treated wood structures, ranging in age continued on page 20
Protecting The Public’s Health From CCA-Treated Wood

Watch out for that greenish-looking wood. Despite a February 2002 agreement between industry and EPA to phase out manufacturing of chromated copper arsenate (CCA) treated wood by the end of 2003, existing stocks of CCA-treated wood, and structures made with it, can continue to be sold and used until supplies are exhausted. CCA is highly toxic to human health and the environment. The arsenic, which migrates to the wood’s surface, and leaches out, contaminating surrounding soil, is a known human carcinogen and has been linked to nervous system damage and birth defects. Chromium VI, also a known carcinogen, can, like arsenic, leach out of the wood, contaminating wood surfaces and surrounding soil. Take precautions to limit exposure to the dangers this wood preservative poses.

Identifying CCA

- Look for a green tint to the wood.
- Look for labels on new wood and wooden structures warning of the presence of arsenic.
- Purchase arsenic testing kits to see if structures and surrounding soil are contaminated. Testing kits are available from Environmental Working Group (www.ewg.org) and The Healthy Building Network (www.healthybuilding.net).
- Contact Beyond Pesticides for further resources concerning assessment.

Limiting Arsenic Exposure

- Do not let children play underneath wooden decks. Also do not store toys or tools that people will touch underneath a deck.
- Always wash hands after handling treated wood.
- Use a tablecloth on a pressure-treated table.
- Seal pressure-treated wood to prevent arsenic from leaching into the environment and contacting people. Water-based latex paint is the safest sealant and should be reapplied every year, depending on local climate.
- Oil-based stains and paints are more durable but also more toxic than water-based.
- Try to avoid paints and sealants that contain volatile organic compounds (VOCs). If you must, choose products with low levels of VOCs.

Less Toxic Alternative Materials

- Other ingredients to avoid in your sealant include formaldehyde, fungicide, heavy metals, preservatives and mildicide.
- Some least-toxic products to try include Bioshield, Miller Paint, and AFM Safe Coat paints.
- Do not treat CCA wood with acid deck wash or brighteners, or cleaners containing bleach, which will hasten the release of arsenic and chromium VI.
- If you think you are experiencing poisoning due to CCA exposure, see a physician or contact the Poison Control Center.

Safe Disposal of CCA

- Currently there is no standard for safely disposing of CCA-treated wood. While studies have shown that new CCA-treated wood routinely leaches enough arsenic to qualify as hazardous waste, it continues to be disposed of in unlined landfills where arsenic could leach into groundwater.
- Contact appropriate local or state agencies for disposal designations in your area.
- Never burn CCA-treated wood. The release of arsenic into the air is highly toxic.
- Do not buy or use CCA-treated wood as mulch. In shredded form it is more likely to leach into the environment and contaminate your property.

from four months to 15 years, contained an overall average chromium concentration of 43 mg/kg (ppm), compared to 20 mg/kg (ppm) for the control soils. The same study found that the overall average arsenic concentration underneath treated decks was 76 mg/kg, compared to only 3.7 mg/kg for the control samples.\textsuperscript{11} In addition, a community group in Ithaca, NY found soil samples under a CCA-treated playset with levels of arsenic up to 101 parts per million (ppm), over ten times the found soil samples under a CCA-treated playset with levels of the lettuce’s arsenic uptake was more than 1.7 parts per million. Lettuce in gardens with CCA-treated woodblocks showed garden containing CCA-treated wood. Research that examines exposure to CCA can occur by eating food raised in a garden containing CCA. Exposures through food grown in contaminated soil: Fur- mation facilities. This can cause the CCA preservative to not fully fix to the wood. Workers have been exposed to massive quantities of arsenic, chromium and copper, causing skin irritation, and increasing risk of chronic health effects.

Exposure through incomplete fixation: Pressure treated wood frequently fails to be fully dried before leaving produc- tion facilities. This can cause the CCA preservative to not fully fix to the wood. Workers have been exposed to massive quantities of arsenic, chromium and copper, causing skin irritation, and increasing risk of chronic health effects.

Exposure through food grown in contaminated soil: Further exposure to CCA can occur by eating food raised in a garden containing CCA-treated wood. Research that exam- ined lettuce in gardens with CCA-treated woodblocks showed the lettuce’s arsenic uptake was more than 1.7 parts per million (ppm) of arsenic by dry weight.\textsuperscript{15} These levels alone may not cause acute poisoning, but when considered as an additive to other exposures, they are far from negligible.

Exposure through inhalation: Dust on a CCA-treated structure, or from the soil below, may be contaminated and contribute to total exposure to CCA if inhaled. In dry cli- mates, dust is easily kicked up and inhaled. Even wet cli- mates can have significant dust and may have higher con- taminated levels in the soil due to past leaching. Most trou- bling is the possibility of inhaling sawdust or fly ash. Al- though these risks may not be present in normal use, its occurrence can have acutely toxic effects and dramatically increase any long-term CCA (or its constituents) body burden. Children’s increased respiration rates can dramati- cally exacerbate these exposures.

**Acute health effects**

Toxic effects of CCA can come from any of the chemical con- stituents, but most of the focus has been on arsenic. Most acute effects can be seen after inhalation or ingestion of ar- senic or arsenic contaminated substrates. Symptoms of acute arsenic toxicity include pain, eye irritation, nausea, vomit- ing, and diarrhea, characteristic skin lesions, decreased pro- duction of red and white blood cells, abnormal heart func-

**Chronic health effects**

Chronic effects of arsenic exposure have been seen in many body systems. Although some health effects are exposure specific, most are systemic and can result from any root. Arsenic poisoning damages mucus membranes, and it pro- duces peripheral nervous system disturbances and degener- ation and hearing loss.\textsuperscript{19} In addition, research links expo- sure with immune system suppression, leaving victims more vulnerable to other ailments.\textsuperscript{20} Studies on rats show increased fetal mortality, cleft pallet and increased ratio of male to female offspring.\textsuperscript{21}

Children face particular risk from exposure to arsenic. A Thailand Health Research Institute study showed an inverse relationship between the levels of arsenic found in children’s hair and their height. This relationship was significant for both high and low arsenic accumulations. This study repre- sents defining data on low-level arsenic exposure’s effect on the growth of children.\textsuperscript{22}

Chromium also poses long-term health threats. Studies of chromium (VI) from industrial emissions have found it to be highly toxic due to strong oxidation characteristics and ready membrane permeability.\textsuperscript{23} Cr (VI) has been known to cause damage to kidneys and liver. Skin contact with cer- tain chromium (VI) compounds can cause skin ulcers. In addition, birth defects have been observed in animals exposed to chromium (VI).\textsuperscript{24}

**Carcinogenic effects**

EPAs Carcinogen Assessment Group classified inorganic arsenic as a Group A carcinogen. Arsenic ingestion and inhalation has been reported to increase the risk of cancer, especially in the liver, bladder, kidney and lung.\textsuperscript{25} The form of chromium (hexavalent) found in CCA has also been found by EPA to be a known human carcinogen. An EPA “Product Matrix” on “Wood Preservatives” states that “inorganic arsenic compounds have been shown to cause cancer in humans.”\textsuperscript{26}

**Neurological effects**

Low dose neurological effects are well-documented with ar- senic exposure. Although past studies have concluded that neurological function was not impaired below 1000 ppb, a recent EPA study found that vibrotactile and pin-prick sensi- tivity were affected at levels as low as 300 ppb in drinking water.\textsuperscript{27} EPA states, “There is a large body of epidemiology studies and case reports which describe neurotoxicity in hu- mans after both acute and chronic exposures...”\textsuperscript{28}
Ecological effects

In addition to human health effects, the arsenicals found in CCA pose grave ecological threats. Many aquatic organisms are extremely sensitive to arsenic exposure, which can result in serious health effects and even death at relatively low levels. Arsenic bioconcentrates in aquatic organisms - in fresh water organisms up to 17 times background levels, and in marine oysters 330 times background levels.29 Because of bioaccumulation, low levels of arsenic pose devastating threats to larger animals including top predators that eat organisms exposed to arsenic. Studies have shown that quantities of arsenic that can leach from CCA-treated wood are high enough to bioaccumulate. This is especially true in soils and water with slightly acidic pH.30

The copper in CCA can be toxic to aquatic life as well. The LC50 for aquatic invertebrates and fish ranges from 5 micrograms (µg) per liter to 100,000 µg l⁻¹.31 Effects on aquatic invertebrates include decreased feeding and egg production and impairment of certain behaviors, such as the ability of clams to burrow.32 In addition, fish growth, spawning and survival are all affected by the presence of copper. Salmon have been known to head back downstream without spawning due to high copper concentration. Gill lesions, kidney damage, and diabetes-like symptoms in a variety of fish species were also observed in association with copper concentrations.33
